CONVEX CXbatch permits users to submit jobs for batch execution in queues. The jobs may be submitted to and executed on either the local machine or a remote machine, depending on the batch system configuration. Different resource quotas may be defined on a queue-by-queue basis. Algorithms are used to schedule jobs for execution on the most lightly loaded processor. CXbatch software relies on two underlying utilities for configuration and control: qmapmgr and qmgr. Individual commands exist within CXbatch to submit, control, and check the status of job requests.

NAME
qchkpnt - checkpoint CXbatch request(s).

SYNOPSIS
qchkpnt [-e freq] [-f] request-id ...

DESCRIPTION
qchkpnt checkpoints the requests whose request-ids are listed on the command line. The current state of all the processes comprising the request are saved in a set of checkpoint files. The checkpoint files are stored in the CXbatch checkpoint directory. A successfully checkpointed request will be restarted from its checkpointed state instead of being re-run.

Only running batch requests may be checkpointed. To checkpoint a request, the invoking user must be the owner of the request or have CXbatch operator privileges.

The options have the following meanings:

-e freq Normally the request is checkpointed immediately. When the -e option is present the request will be checkpointed periodically at intervals of freq.

The freq is specified as <[number] unit>, where number is a positive integer and unit is [Hours | Days | Weeks]. A number of zero will cancel periodic checkpointing.

-f Force checkpoint even if one of the processes of the request hold non-checkpointable resources.

DIAGNOSTICS
qchkpnt returns an exit status describing what it did. If there were no errors, the exit status is zero. If one or more of the requests weren’t checkpointed, the exit status is the number of requests that weren’t checkpointed. If a fatal error occurs and none of the requests are checkpointed (e.g., a syntax error), the exit status is one of the codes defined in <sysexits.h>.

EX_USAGE The command was used incorrectly, e.g., with the wrong number of arguments, a bad flag, a bad syntax in a parameter.

EX_OSFILE Some batch system file does not exist, cannot be opened, or has an error.

EX_TEMPFAIL Temporary failure; retry the command at a later time.

EX_NOPERM You did not have sufficient permission to perform the operation.

EX_SOFTWARE Too many request-ids were specified.

NAME
qdel – delete or signal CXbatch request(s).

SYNOPSIS
qdel [-k] [-signo] [-u username] request-id[@ host] ...

DESCRIPTION
qdel deletes all queued CXbatch requests whose request-ids are listed on the command line. Additionally, if the flag -k is specified, the default signal of SIGKILL (9) is sent to any running request whose request-id is listed on the command line. This causes the receiving request to exit and be deleted. If the flag -signo is present, the specified signal is sent instead of the SIGKILL signal to any running request whose request-id is listed on the command line. signo can be either the signal number or the signal name. The signal names are as given in /usr/include/signal.h, stripped of the common SIG prefix. In the absence of the -k and -signo flags, qdel will not delete a running CXbatch request.

To delete or signal a CXbatch request, the invoking user must be the owner (the submitter of the request) or the superuser. The only exception to this rule occurs when the invoking user has CXbatch operator privileges as defined in the CXbatch manager database. Under these conditions, the invoker may specify the -u username flag that allows the invoker to delete or signal requests owned by the user whose account name is username. When this form of the command is used, all request-ids listed on the command line are presumed to refer to requests owned by the specified user.

A CXbatch request is always uniquely identified by its request-id, no matter where it is in the network of the machines. A request-id is always of the form seqno or seqno.hostname, where hostname identifies the machine from whence the request was originally submitted, and seqno identifies the sequence number assigned to the request on the originating host. If the hostname portion of a request-id is omitted, the local host is always assumed. The local host is searched for each given request-id, unless a different host is specified with @ host.

The request-id of any CXbatch request is displayed when the request is first submitted (unless the silent mode of operation for the given CXbatch command was specified). The user can also obtain the request-id of any request through the use of the qstat(1) command.

DIAGNOSTICS
qdel returns an exit status describing what it did. If there were no errors, the exit status is zero.
If one or more of the requests were not deleted, the exit status is the number of requests that weren’t deleted. If a fatal error occurs and none of the requests are deleted (e.g., a syntax error), the exit status is one of the codes defined in <sys/exits.h>.

EX_USAGE The command was used incorrectly, e.g., with the wrong number of arguments, a bad flag, a bad syntax in a parameter.

EX_NOUSER The user specified with -u did not exist.

EX_NOHOST The host specified did not exist.

EXOfFile Some batch system file does not exist, cannot be opened, or has an error.

EX_TEMPFAIL Temporary failure; retry the request at a later time.

EX_NOPERM You did not have sufficient permission to perform the operation.

EX_SOFTWARE Too many request-ids were specified.

CAVEATS
When a CXbatch request is signaled by the methods discussed above, the proper signal is sent to all processes comprising the CXbatch request that are in the same process group. Whenever a CXbatch request is spawned, a new process group is established for all processes in the request. However, should one or more processes of the request successfully execute a setpgrp() system call,
such processes will not receive any signals sent by the qdel(1) command. This can lead to "rogue" request processes that must be killed by other means such as the kill(1) command.

NOTES
CXbatch is an optional product; for more information, contact your CONVEX sales representative.
NAME
qjlist – list the commands in a batch job.

SYNOPSIS
qjlist request-id[@ host] ...

DESCRIPTION
qjlist lists the commands in each CXbatch request whose request-ids are listed on the command line. To list the commands in a CXbatch request, the invoking user must be the owner (the submitter of the request). The only exception to this rule occurs when the invoking user is the superuser or has CXbatch operator privileges as defined in the CXbatch manager database. Under these conditions, the invoker may specify any batch request.

A CXbatch request is always uniquely identified by its request-id. A request-id is always of the form seqno or seqno.hostname, where hostname identifies the machine from whence the request was originally submitted, and seqno identifies the sequence number assigned to the request on the originating host. If the hostname portion of a request-id is omitted, the local host is always assumed. The local host is searched for each given request-id unless a different host is specified with @ host.

The request-id of any CXbatch request is displayed when the request is first submitted (unless the silent mode of operation for the given CXbatch command was specified). The user can also obtain the request-id of any request through the use of the qstat(I) command.

qjlist returns an exit status describing what it did. If there were no errors, the exit status is zero. If one or more of the requests were not listed, the exit status is the number of requests that weren’t listed. If a fatal error occurs and none of the requests are listed (e.g., a syntax error), the exit status is one of the codes defined in <sysexits.h>.

EX_USAGE The command was used incorrectly, e.g., with the wrong number of arguments, a bad flag, or bad syntax in a parameter.

EX_NOHOST The host specified did not exist.

EX_OSFIL£ Some batch system file does not exist, cannot be opened, or has an error.

EX_NOPERM You did not have sufficient permission to perform the operation.

NAME
qlimit - show supported batch limits, and shell strategy for the named host(s).

SYNOPSIS
qlimit [ host-name ... ]

DESCRIPTION
qlimit displays the set of batch request resource limit types that can be directly enforced on the
implied local host or named hosts and also the batch request shell strategy defined for the implied
local host or named hosts.

If no host-names are given, the information displayed is relevant to only the local host. Otherwise, the supported batch request limits, and batch request shell strategy for each of the named
hosts is displayed.

CXbatch supports many batch request resource limit types that can be applied to a batch request. However, not all UNIX implementations are capable of supporting the rather extensive set of limit
types that CXbatch provides.

The set of limits applied to a batch request is always restricted to the set of limits that can be
directly supported by the underlying UNIX implementation. If a batch request specifies a limit
that cannot be enforced by the underlying UNIX implementation, the limit is ignored, and the
batch request operates as though there were no limit (other than the obvious physical maximums)
placed upon that resource type.

When an attempt is made to queue a batch request, each limit-value specified by the request (that
can also be supported by the local UNIX implementation) is compared against the corresponding
limit-value configured for the destination batch queue. If the corresponding batch queue limit-value
for all batch request limit-values is defined as unlimited, or is greater than or equal to the
corresponding batch request limit-value, the request can be successfully queued, provided that no
other anomalous conditions occur. For request infinity limit-values, the corresponding queue
limit-value must also be configured as infinity.

These resource limit checks are performed irrespective of the batch request arrival mechanism,
either by a direct use of the qsub(1) command, or by the indirect placement of a batch request
into a batch queue via a pipe queue. It is impossible for a batch request to be queued in a
CXbatch batch queue if any of these resource limit checks fail.

Finally, if a request fails to specify a limit-value for a resource limit type supported on the execution
machine, the corresponding limit-value, as configured for the destination queue, becomes the
limit-value for the unspecified request limit.

Upon the successful queuing of a request in a batch queue, the set of limits under which the
request will execute is frozen and will not be modified by subsequent qmgr(8) commands that
alter the limits of the containing batch queue.

As mentioned above, this command also displays the shell strategy configured for the implied
local host or named hosts. In the absence of a shell specification for a batch request, CXbatch
must choose which shell should be used to execute that batch request. CXbatch supports three
different algorithms, or strategies, to solve this problem that can be configured for each system by
a system administrator, depending on the needs of the user's involved, and upon system performance criterion.

The three possible shell strategies are called:

- fixed
- free
- login
These shell strategies respectively cause the configured fixed shell to be exec'd to interpret all batch requests; cause the user's login shell as defined in the password file to be exec'd, which in turn chooses and spawns the appropriate shell for running the batch shell script; or cause only the user's login shell to be exec'd to interpret the script.

A shell strategy of fixed means that the same shell chosen by the system administrator is used to execute all batch requests (in the absence of a shell specification).

A shell strategy of free runs the batch request script exactly as would an interactive invocation of the script and is the default CXbatch shell strategy.

The strategies of fixed and login exist for host systems that are short on available free processes. In these two strategies, a single shell is exec'd, and that same shell is the shell that executes all of the commands in the batch request shell script.

When a shell strategy of fixed has been configured for a particular CXbatch system, the "fixed" shell that will be used to run all batch requests at that host is displayed.

DIAGNOSTICS
qlimit returns an exit status describing what it did. If there were no errors, the exit status is zero. If one or more of the hosts were invalid or couldn't be reached, the exit status is the number of hosts that were invalid or couldn't be reached. If a fatal error occurs, the exit status is one of the codes defined in <sysexits.h>.

EX_OSFILE Some batch system file does not exist, cannot be opened, or has an error.

NAME
qps – display process status of CXbatch related processes

SYNOPSIS
qps [ queue-name ... ]
qps -r request-id
qps -{p|q} process-id

DESCRIPTION
qps prints information about CONVEX CXbatch related processes.
If no queues are specified, information is printed about all CXbatch related processes, including
the daemon processes. Otherwise, information is printed for the specified queues only. Only
batch queues on the local system are significant; pipe queues and remote queues do not have
processes running on the local system.
Information about processes pertaining to a particular request can be obtained by using the -r
request-id option. Only a single request-id can be specified.
For each process, qps prints the queue name (QUEUE), the request ID (REQ), the process ID
(PID), the state (STAT) of the process, CPU time (TIME) used by the process (including both
user and system time) and which command is running (COMMAND). More information about
these fields can be found on the ps(1) man page.
Using the -p process-id option, you can inquire whether a particular process is running from
within the CXbatch system. If it is, a line is printed stating the queue and request to which the
process is related and qps exits with a status of 0. Otherwise, you are informed that the process
is not running from within the CXbatch system and qps exits with a status of 1. For the pur­
poses of this inquiry, the top level daemons are not considered to be running under the CXbatch
system, but the CXbatch shepherd processes are.
The -q process-id option is a silent version of the -p option. Nothing is printed, but the exit
status of qps is set appropriately. Only a single process-id can be specified for either of these
options.

DIAGNOSTICS
qps returns an exit status of 0 if no errors occur, unless the the -p or -q options are specified, in
which case the exit status is 0 or 1 as described above. If a fatal error occurs, the exit status is
one of the codes defined in <sys/exits.h>.

EX_USAGE The command was used incorrectly, e.g., with the wrong number of argu­
ments, a bad flag, a bad syntax in a parameter.

EX_OSERR An internal call to ps(1) failed. If this error occurs, first make sure a '/bin/ls
laxwg' returns valid output, then check the status of CXbatch.

NOTES
CXbatch is an optional product; for more information, contact your CONVEX sales representa­
tive.
NAME
qrestart — restart checkpointed CXbatch request(s).

SYNOPSIS
qrestart [-f] [ request-id ]

DESCRIPTION
qrestart restarts the requests whose request-ids are listed on the command line.
Only successfully checkpointed requests may be restarted. To restart a request, the invoking user
must be the owner of the request or have CXbatch operator privileges.
qrestart is typically only used if the automatic restart of the request by CXbatch failed.
The options have the following meanings:
-f Force restart of request even if non-restartable conditions exist in any of the processes of
the request.

DIAGNOSTICS
qrestart returns an exit status describing what it did. If there were no errors, the exit status is
zero. If one or more of the requests were not restarted, the exit status is the number of requests
that weren’t restarted. If a fatal error occurs and none of the requests are restarted (e.g., a syn­
tax error), the exit status is one of the codes defined in <sys/exit.h>.

EX_USAGE The command was used incorrectly, e.g., with the wrong number of argu­
ments, a bad flag, a bad syntax in a parameter.

EX_OSFILE Some batch system file does not exist, cannot be opened, or has an error.

EX_TEMPFAIL Temporary failure; retry the command at a later time. EXSOFTWARE
Too many request-ids were specified.

NAME
  qstat – display status of CXbatch queue(s)

SYNOPSIS
  qstat [-a] [-I] [-m] [-u user-name] [-x] [queue-name ...] [queue-name@host-name ...]

DESCRIPTION
  qstat displays the status of CONVEX CXbatch queues.

  If no queues are specified, the current state of each CXbatch queue on the local host is displayed. Otherwise, information is displayed for the specified queues only. Queues may be specified either as queue-name or queue-name@host-name. In the absence of a host-name specifier, the local host is assumed.

  For each selected queue, qstat displays a queue header (information about the queue itself) followed by information about requests in the queue. Ordinarily, qstat shows only those requests belonging to the invoker. The following flags are available:

  -a       Shows all requests.
  -l       Requests are shown in a long format.
  -m       Requests are shown in a medium-length format.
  -u user-name       Shows only those requests belonging to user-name.
  -x       The queue header is shown in an extended format.

  The queue header always includes the queue-name, queue type, queue status (see below), an indication of whether or not the queue is pipeonly (accepts requests from pipe queues only), and the number of requests in the queue. An extended queue header also displays the priority and run limit of a queue, as well as the access restrictions, cumulative use statistics, server and destinations (if a pipe queue), and resource limits (if a batch queue).

  By default, qstat displays the following information about a request: the request-name, the request-id, the owner, the relative request priority, and the current request state (see below). For running requests, the process group is also shown, as soon as it becomes available to the local CXbatch daemon.

  qstat -m shows the following additional information: if the request was submitted with the constraint that it not run before a certain time and date, the constraining time and date are also displayed.

  qstat -I shows the time at which the request was created, an indication of whether or not mail will be sent, where mail will be sent, and the user name on the originating machine. If a batch queue is being examined, resource limits, planned disposition of stderr and stdout, any advice concerning the command interpreter, and the umask value are shown.

  The relative ordering of requests within a queue does not always determine the order in which the requests are run. The CXbatch request scheduler is allowed to make exceptions to the request ordering for the sake of efficient machine resource usage. However, requests appearing near the beginning of the queue have higher priority than requests appearing later, and are usually run before requests appearing later on in the queue.

  QUEUE STATE
  The general state of a queue is defined by two principal properties of the queue.

  The first property determines whether or not requests can be submitted to the queue. If they can, the queue is said to be enabled. Otherwise the queue is said to be disabled. One of the words CLOSED, ENABLED, or DISABLED appears in the queue status field to indicate the respective queue states of: enabled (with no local CXbatch daemon), enabled (and local CXbatch daemon is present), and disabled. Requests can only be submitted to the queue if the queue is enabled and the local CXbatch daemon is present.
The second principal property of a queue determines if requests that are ready to run, but are not now presently running, will be allowed to run upon the completion of any currently running requests, and whether any requests are presently running in the queue.

If queued requests not already running are blocked from running, and no requests are presently executing in the queue, the queue is said to be stopped. If the same situation exists with the difference that at least one request is running, the queue is said to be stopping, where the requests presently executing will be allowed to complete execution, but no new requests will be spawned.

If queued requests ready to run are only prevented from doing so by the CXbatch request scheduler, and one or more requests are presently running in the queue, the queue is said to be running. If the same circumstances prevail with the exception that no requests are presently running in the queue, the queue is said to be inactive. Finally, if the CXbatch daemon for the local host upon which the queue resides is not running, but the queue would otherwise be in the state of running or inactive, the queue is said to be shutdown. The queue states describing the second principal property of a queue are therefore respectively displayed as STOPPED, STOPPING, RUNNING, INACTIVE, and SHUTDOWN.

REQUEST STATE

The state of a request may be arriving, holding, waiting, queued, routing, running, departing, or exiting.

- **arriving**  The request is being enqueued from a remote host.
- **holding**   The request is presently prevented from entering any other state (including the running state), because a hold has been placed on the request.
- **waiting**   The request was submitted with the constraint that it not run before a certain date and time, and that date and time have not yet arrived.
- **queued**    The request is eligible to proceed (by routing or running).
- **routing**   The request has reached the head of a pipe queue and is receiving service.
- **departing** A request is departing from the time the pipe queue turns to other work until the request has arrived intact at its destination.
- **running**   The request has reached its final destination queue and is actually executing.
- **exiting**   The batch request has completed execution and will exit from the system after the required output files have been returned (to possibly remote machines).

Imagine a batch request originating on a workstation, destined for the batch queue of a computation engine, to be run immediately. That request would first go through the states queued, routing, and departing in a local pipe queue. Then it would disappear from the pipe queue. From the point of view of a queue on the computation engine, the request would first be arriving, then queued, running, and finally exiting. Upon completion of the exiting phase of execution, the batch request would disappear from the batch queue.

DIAGNOSTICS

`qstat` returns an exit status describing what it did. If there were no errors, the exit status is zero. If one or more of the queues were not listed, the exit status is the number of queues that weren’t listed. If a fatal error occurs and none of the queues are listed (ex, a syntax error), the exit status is one of the codes defined in `<sys/exit.h>`.

- **EX_USAGE** The command was used incorrectly, e.g., with the wrong number of arguments, a bad flag, a bad syntax in a parameter.
- **EX_NOUSER** The user specified with `-u` did not exist.
EX_OSFILE Some batch system file does not exist, cannot be opened, or has an error.

NOTES
CXbatch is an optional product; for more information, contact your CONVEX sales representative.
NAME
qsub – submit a CXbatch request.

SYNOPSIS
qsub [ flags ] [ script-file ]

DESCRIPTION
qsub submits a batch request to CONVEX CXbatch.

If no script-file is specified, the set of commands to be executed as a batch request is taken directly from the standard input file (stdin). In all cases however, the script file is spooled, so that later changes will not affect previously queued batch requests.

All of the flags that can be specified on the command line can also be specified within the first comment block inside the batch request script file as embedded default flags. Such flags appearing in the batch request script file set default characteristics for the batch request. If the same flag is specified on the command line, the command line flag (and any associated value) takes precedence over the embedded flag. See the section entitled LONG DESCRIPTION for more information on embedded default flags.

What follows is a terse definition of the flags implemented by the qsub command (see the section LONG DESCRIPTION for the complete definition and syntax used for each of these flags).

- a – run request after stated time
- b – set the billing activity for request
- c – request is checkpointable
- cp – specify periodic checkpoint frequency
- e – direct stderr output to stated destination
- eo – direct stderr output to the stdout destination
- h – put request on hold after submitting
- i – request requires current directory to be imported
- ke – keep stderr output on the execution machine
- ko – keep stdout output on the execution machine
- l – run request under a login shell
- lx – establish a resource limit
- mb – send mail when the request begins execution
- me – send mail when the request ends execution
- mu – send mail for the request to the stated user
- ni – don’t import the current directory
- nr – declare that batch request is not restartable
- nc – request is not checkpointable
- o – direct stdout output to the stated destination
- p – specify intra-queue request priority
- q – queue request in the stated queue
- r – assign stated request name to the request
- s – specify shell to interpret the batch request script
- t – signal process when the job completes
- x – export all environment variables with request
- y – append accounting data to stdout output file
- z – submit the request silently

If you request that a batch request be run under a login shell, the system and user startup files will be read (/etc/login and ~/.login for C-shell or /etc/profile and $HOME/.profile for Bourne shell). A C-shell login shell will also read /etc/logout and ~/.logout while exiting. The ~/.cshrc file is read by the C-shell regardless of whether or not it is executed as a login shell.
The environment string ENVIRONMENT=BATCH is added to the environment so that shell
scripts (and the user's .profile (Bourne shell) or .cshrc and .login (C-shell) scripts), can test for
batch request execution when appropriate, and not (for example) perform any setting of terminal
characteristics, because a batch request is not connected to an input terminal. For example, if
your login shell is C-shell, the following .login file prevents stty, tset, and msgs from being run
during batch jobs.

if (! $?ENVIRONMENT) then
    stty crt erase 'H kill 'U
    tset -Q
    msgs -q
endif

If your login shell is Bourne shell, the following .profile file has the same effect.

if test "$ENVIRONMENT" != "BATCH"
then
    stty crt erase 'H kill 'U
    tset -Q
    msgs -q
fi

When CXbatch is configured on more than one machine, it is possible for users to submit jobs to
remote machines in the batch network. However, CXbatch must ensure that the submitter has
permission to access the remote machine. This is accomplished with the user equivalence mechanism described in hosts.equiv(5) (the same method that is used by rlogin and rsh). If the machines in the batch network are not equivalenced in the /etc/hosts.equiv file, users must create a .rhosts file in their home directories. If this is not done, the submitter will not have access to the remote
machine. Read the hosts.equiv(5) man page for more information.

LONG DESCRIPTION

As described above, it is possible to specify default flags within the batch request script file that
configure the default behavior of the batch request. The algorithm used to scan for such embedded default flags within a batch request script file is:

1. Read the first line of the script file.
2. If the current line contains only whitespace characters, or the first non-whitespace character of the line is "":", goto step 7.
3. If the first non-whitespace character(s) of the current line is not "#" or "$!", goto step 8.
4. If the second non-whitespace character in the current line is not the "@" character, or the character immediately following the second non-whitespace character in the current line is not a "$", goto step 7.
5. If no "-" is present as the character immediately following the "@" sequence, goto step 8.
6. Process the embedded flag, stopping the parsing process upon reaching the end of the line, or upon reaching the first unquoted "#" or "$!" character(s).
8. End. No more embedded flags are recognized.

Here is an example of the use of embedded flags within the script file.
Batch request script example:
#
@$-a "11:30pm EDT" -lt "21:10, 20:00"
# Run request after 11:30 EDT by default,
# and set a maximum per-process CPU time
# limit of 21 minutes and ten seconds.
# Send a warning signal when any process
# of the running batch request consumes
# more than 20 minutes of CPU time.
#$-lt 1:45:00
# Set a maximum per-process CPU time limit
# of one hour, and 45 minutes. (The
# implementation of CPU time limits is
# completely dependent upon the UNIX
# implementation at the execution
# machine.)
#$-mb -me # Send mail at beginning and end of
# request execution.
#$-q batch1 # Queue request to queue: batch1 by
# default.
#$ # No more embedded flags.

make all

The following paragraphs give detailed descriptions of the flags supported by the qsub command.

-\texttt{-a date-time} Do not run the batch request before the specified date and/or time. If a \texttt{date-time} specification is composed of two or more tokens separated by whitespace characters, the \texttt{date-time} specification must be placed within double quotes as in \texttt{-a "July, 4, 2026 12:31-EDT"} or otherwise escaped such that \texttt{qsub} and the shell will interpret the entire \texttt{date-time} specification as a single-character string. This restriction also applies when an embedded default \texttt{-a} flag with accompanying \texttt{date-time} specification appears within the batch request script file.

The syntax accepted for the \texttt{date-time} parameter is relatively flexible. Unspecified date and time values default to an appropriate value (e.g., if no date is specified, the current month, day, and year are assumed).

A date may be specified as a month and day (current year assumed), or the year can also be explicitly specified. It is also possible to specify the date as a weekday name (e.g., \texttt{"Tues"}), or as one of the strings: \texttt{"today"} or \texttt{"tomorrow"}. Weekday names and month names can be abbreviated by any three-character (or longer) prefix of the actual name. An optional period can follow an abbreviated month or day name.

Time of day specifications can be given using a twenty-four hour clock, or \texttt{"am"} and \texttt{"pm"} specifications may be used. In the absence of a meridian specification, a twenty-four hour clock is assumed.

It should be noted that the time of day specification is interpreted using the precise meridian definitions whereby \texttt{"12am"} refers to the twenty-four hour clock time of 0:00:00, \texttt{"12m"} refers to noon, and \texttt{"12-pm"} refers to 24:00:00. Alternatively, the phrases \texttt{"midnight"} and \texttt{"noon"} are accepted as time of day specifications, where \texttt{"midnight"} refers to the time of 24:00:00.

A time zone may also appear at any point in the \texttt{date-time} specification. Thus, it is legal to say: \texttt{"April 1, 1987 18:01-PDT"}. In the absence of a time zone specification, the local time zone is assumed, with daylight savings time being inferred when appropriate, based on the date specified.

All alphabetic comparisons are performed in a case insensitive fashion such that both \texttt{"WeD"} and \texttt{"weD"} refer to the day of Wednesday.
Some valid date-time examples are:

- **01-Jan-1986 12am, PDT**
- **Tuesday, 22:00:00**
- **11pm tues.**
- **tomorrow 23:00-MST**

### `-b [group.] activity`

Set the billing activity for request. The `group` and `activity` arguments refer to entries in the `/etc/group` and `/etc/activities` files respectively. The `group. activity` combination must correspond to an entry in the `/etc/actwho` file. If `group` is omitted, the current primary group of the submitting user is assumed. A request always runs under the submitting user’s default group. The `group` argument to this option is used only in verifying a user’s access to the selected `activity`. See the `bill(1)` man page for more information.

### `-c`

Specify that this request is checkpointable. A request queued with this flag is checkpointed automatically before a CXbatch shutdown, and may be explicitly checkpointed using CXbatch commands.

### `-cp period`

Declare that this request should be checkpointed periodically by CXbatch at intervals of `period`. The `period` is specified as `<number unit>`, where `number` is a positive integer and `unit` is `[Hours | Days | Weeks]`.

### `-e [machine:][/path/] stderr-filename`

Direct output generated by the batch request which is sent to the `stderr` file to the named `[machine:][/path/] stderr-filename`.

The brackets “[” and “]” enclose optional portions of the `stderr` destination `machine`, `path`, and `stderr-filename`.

If no explicit `machine` destination is specified, the destination machine defaults to the machine that originated the batch request or to the machine that will eventually run the request, depending on the respective absence or presence of the `-ke` flag.

If no `machine` destination is specified, and the path/filename does not begin with a “/”, the current working directory is prepended to create a fully qualified path name, provided that the `-ke` (keep `stderr`) flag is also absent. In all other cases, any partial path/filename is interpreted relative to the user’s home directory on the `stderr` destination machine.

This flag cannot be specified when the `-eo` flag option is also present.

If the `-eo` and `-e [machine:][/path/] stderr-filename` flag options are not present, all `stderr` output for the batch request is sent to the file whose name consists of the first seven characters of the `request-name` followed by the characters: “.e”, followed by the request sequence number portion of the `request-id` discussed below. In the absence of the `-ke` flag, this default `stderr` output file is placed on the machine that originated the batch request in the current working directory, as defined when the batch request was first submitted. Otherwise, the file is placed in the user’s home directory on the execution machine.

### `-eo` (default)

Direct all output that would normally be sent to the `stderr` file to the `stdout` file for the batch request. This flag cannot be specified when the `-e [machine:][/path/] stderr-filename` flag option is also present.

### `-h`

Put request on hold after submitting. The request is put into a HOLD (user hold) rather than a QUEUED state at the time of submittal. The hold can be removed using the `qmgr(8)` ‘RELease Request’ command.

### `-i`

Some jobs may require access to files located in the directory from which a job is
submitted. This option tells CXbatch that the current working directory should be imported before running this job. If the execution queue is on the same machine as the current working directory, CXbatch will change directories before starting the job. However, if the execution queue is on another machine, CXbatch will import the current directory with NFS. **NOTE:** CXbatch will make temporary NFS mounts into the /tmp filesystem. Care should be taken that any automatic cleanup operations on the /tmp filesystem do not traverse NFS mount points.

```-ke```

In the absence of an explicit `machine` destination for the `stderr` file produced by a batch request, the `machine` destination chosen for the `stderr` output file is the machine that originated the batch request. In some cases, however, this behavior may be undesirable, so the `-ke` flag can be specified which instructs CXbatch to leave any `stderr` output file produced by the request on the machine that actually executed the batch request.

This flag is meaningless if the `-eo` flag is specified and cannot be specified if an explicit `machine` destination is given for the `stderr` parameter of the `-e` flag.

```-ko```

In the absence of an explicit `machine` destination for the `stdout` file produced by a batch request, the `machine` destination chosen for the `stdout` output file is the machine that originated the batch request. In some cases, however, this behavior may be undesirable, and so the `-ko` flag can be specified which instructs CXbatch to leave any `stdout` output file produced by the request on the machine that actually executed the batch request.

This flag cannot be specified if an explicit `machine` destination is given for the `stdout` parameter of the `-o` flag.

```-l```

The submitted request will be run under a login shell. This was the default behavior in the V1.0 release of CXbatch, but is now only done if explicitly requested. See the discussion above regarding shell start-up files and refer to the appropriate shell man page for details on the differences between login and non-login shells. **NOTE:** Running a job request under a login C-shell will cause the C-shell to issue a warning into the request's output file. This is a function of the C-shell that cannot be suppressed by CXbatch.

```-lx limit-argument```

Set a resource limit. Available limits are summarized in the following table.

<table>
<thead>
<tr>
<th>Resource Limits</th>
<th>Limit option;Limited resource;Enforcement</th>
</tr>
</thead>
<tbody>
<tr>
<td>-le</td>
<td>size-limit;per-process corefile size;truncation</td>
</tr>
<tr>
<td>-ld</td>
<td>size-limit[,warn-limit];per-process data-segment;request denied</td>
</tr>
<tr>
<td>-lf</td>
<td>size-limit[,warn-limit];per-process perm-file;SIGXFSZ</td>
</tr>
<tr>
<td>-ls</td>
<td>size-limit[,warn-limit];per-request perm-space;none</td>
</tr>
<tr>
<td>-lm</td>
<td>size-limit[,warn-limit];per-process memory;none</td>
</tr>
<tr>
<td>-ln</td>
<td>nice-value;per-process nice value; setpriority(2)</td>
</tr>
<tr>
<td>-lt</td>
<td>time-limit[,warn-limit];per-process CPU time;SIGXCPU</td>
</tr>
<tr>
<td>-lw</td>
<td>size-limit[,warn-limit];per-process working set;paging</td>
</tr>
</tbody>
</table>

The `per-process corefile size limit` sets the maximum size of a corefile created by a process. The `per-process data-segment size limit` sets the maximum size to which a process's data-segment can grow. The `per-process perm-file size limit` sets the maximum size to which a permanent file written to by a process can grow. The `per-request perm-file space limit` sets the maximum file space which can be used by permanent files opened for writing by all of the processes in a batch request. The `per-process memory size limit` sets the maximum amount of memory a process can
consume. The _per-request memory space limit_ sets the maximum amount of memory which can be used by all of the processes in a batch request. The _per-process nice value_ sets the nice value for all processes comprising the running batch request. The _per-process stack-segment size limit_ sets the maximum size to which a process's stack-segment can grow. The _per-process CPU time limit_ sets the maximum amount of CPU time a process can consume. The _per-request CPU time limit_ sets the maximum amount of CPU time all of the processes that constitute a batch request can consume. The _per-process temp-file size limit_ sets the maximum size to which a temporary file written to by a process can grow. The _per-request temp-file space limit_ sets the maximum file space which can be used by temporary files opened for writing by all of the processes in a batch request. The _per-process working set size limit_ sets the maximum amount of physical memory each process within a running batch request should use.

Enforcement of limits is done by the underlying UNIX implementation, normally through termination by a signal. Per-process limits are enforced only on the process exceeding the limit; per-request limits are enforced on all the processes which make up a request. The optional warning limits allow warning notification to be made processes where such warnings are supported by the underlying UNIX implementation. Not all UNIX implementations support all the resource limits listed above. The _qsub_ command will pass all specified limits on to the destination machine. If a batch request specifies a limit, and the machine upon which the batch request is eventually run does not support the enforcement of that limit, the limit is simply ignored.

The 'Enforcement' column of the table above indicates the ConvexOS specific enforcement policy of each resource limit. At this time, all _warn-limits_ are treated identically to the hard limits. ConvexOS makes no distinction between permanent and temporary files; all files are treated as permanent.

See the section entitled LIMITS for more information on the implementation of batch request limits and for a description of the precise syntax of the various limit arguments.

- **-mb** Send mail to the user on the originating machine when the request begins execution. If the _-mu_ flag is also present, mail is sent to the user specified for the _-mu_ flag instead of to the invoking user.

- **-me** Send mail to the user on the originating machine when the request has ended execution. If the _-mu_ flag is also present, mail is sent to the user specified for the _-mu_ flag instead of to the invoking user.

- **-mu user-name**
  Specify that any mail concerning the request should be delivered to the user _user-name_. _user-name_ may be formatted either as _user_ (containing no ' @ ' characters), or as _user@machine_. In the absence of this flag, any mail concerning the request is sent to the invoker on the originating machine.

- **-ni** A queue can be configured so that it tries to import the originating directory of each job it runs. If this option is specified, CXbatch does not import the current directory.

- **-nc** Advise CXbatch that this request is not checkpointable. A request queued with this option will not be checkpointed at CXbatch shutdown, nor is it possible to checkpoint the request with any other CXbatch commands.

- **-nr** Declare that the request is non-restartable. If this flag is specified, the request is not restarted by CXbatch upon system boot if the request was running at the time of a CXbatch shutdown or system crash.
By default, CXbatch assumes that all requests are restartable, with the caveat that it is the responsibility of the user to ensure that the request will execute correctly if restarted, by use of appropriate programming techniques.

Requests that are not running are always preserved across host crashes and CXbatch shutdowns for later requeuing, with or without this flag.

When CXbatch is shutdown by an operator command to the qmgr(8) CXbatch control program, a SIGTERM signal is sent to all processes in all running CXbatch requests on the local host, and all queued CXbatch requests are barred from beginning execution. After a finite number of seconds have elapsed (typically sixty, but this value can be overridden by the operator), all remaining processes in all remaining running CXbatch requests are killed by the signal SIGKILL.

For a CXbatch request to be properly restarted after a CXbatch shutdown, the -nr flag must not be specified, and the spawned batch request shell must ignore SIGTERM signals (which is done by default). The spawned batch request shell also must not exit before the final SIGKILL arrives. Because the batch request shell is spawning commands and programs, waiting for their completion, this implies that the commands and programs being executed by the batch request shell must also be immune to SIGTERM signals, saving state as appropriate before being killed by the final SIGKILL signal.

See the CAVEATS section below for more discussion about the restartability of batch requests.

-o [machine:][/path/] stdout-filename
Direct output generated by the batch request which is sent to the stdout file to the named [machine:][/path/] stdout-filename

The brackets "[" and "]" enclose optional portions of the stdout destination machine, path, and stdout-filename.

If no explicit machine destination is specified, the destination machine defaults to the machine that originated the batch request or to the machine that will eventually run the request, depending on the respective absence or presence of the -ko flag.

If no machine destination is specified, and the path/filename does not begin with a "/", the current working directory is prepended to create a fully-qualified path name, provided that the -ko (keep stdout) flag is also absent. In all other cases, any partial path/filename is interpreted relative to the user's home directory on the stdout destination machine.

If no -o [machine:][/path/] stdout-filename flag is specified, all stdout output for the batch request is sent to the file whose name consists of the first seven characters of the request-name followed by the characters: ".o", followed by the request sequence number portion of the request-id discussed below. In the absence of the -ko flag, this default stdout output file is placed on the machine that originated the batch request in the current working directory, as defined when the batch request was first submitted. Otherwise, the file is placed in the user's home directory on the execution machine.

-p priority
Assign an intra-queue priority to the request. The specified priority must be an integer, and must be in the range [0..63], inclusive. A value of 63 defines the highest intra-queue request priority, while a value of 0 defines the lowest. This priority does not determine the execution priority of the request. This priority is only used to determine the relative ordering of requests within a queue.

When a request is added to a queue, it is placed at a specific position within the queue such that it appears ahead of all existing requests whose priority is less than
the priority of the new request. Similarly, all requests with a higher priority remain ahead of the new request when the queuing process is complete. When the priority of the new request is equal to the priority of an existing request, the existing request takes precedence over the new request.

If no *intra-queue* priority is chosen by the user, CXbatch assigns a default value.

The CXbatch manager can assign a maximum request priority on a per queue basis. The maximum request priority is a ceiling on priorities of requests submitted to that queue. A request that specifies a priority higher than the maximum for that queue has its priority lowered to the maximum.

```
-q queue-name[@host]
```

Specify the queue to which the batch request is to be submitted. If no `-q queue-name[@host]` specification is given, the user's environment variable set is searched for the variable `QSUB_QUEUE`. If this environment variable is found, the character string value for `QSUB_QUEUE` is presumed to name the queue to which the request should be submitted. If the `QSUB_QUEUE` environment variable is not found, the request is submitted to the default batch request queue, if defined by the local system administrator. Otherwise, the request cannot be queued, and an appropriate error message is displayed. The `host` specifies the host where the queue resides. If no `host` is given, the local host is assumed. Not all hosts accept remote submissions.

```
-r request-name
```

Assign the specified `request-name` to the request. In the absence of an explicit `-r request-name` specification, the `request-name` defaults to the name of the script file (leading path name removed) given on the command line. If no script file was given, the default `request-name` assigned to the request is `STDIN`.

In all cases, if the `request-name` is found to begin with a digit, the character "R" is prepended to prevent a `request-name` from beginning with a digit. All `request-names` are truncated to a maximum length of 15 characters.

```
-s shell-name
```

Specify the absolute path name of the shell that is used to interpret the batch request script. This flag unconditionally overrides any *shell strategy* configured on the execution machine for selecting which shell to spawn in order to interpret the batch request script.

In the absence of this flag, the CXbatch system at the execution machine uses one of three distinct *shell choice strategies* for the execution of the batch request. Any one of the three strategies can be configured by a system administrator for each CXbatch machine.

The three shell strategies are called:

- `fixed`
- `free`
- `login`

These shell strategies respectively cause the configured `fixed` shell to be exec'd to interpret all batch requests; cause the user's login shell as defined in the password file to be exec'd, which in turn chooses and spawns the appropriate shell for interpreting the batch request script; or cause only the user's login shell to be exec'd to interpret the script.

A shell strategy of `fixed` means that the same shell (as configured by the system administrator) is used to execute all batch requests.
A shell strategy of free runs the batch request script exactly as would an interactive invocation of the script and is the default CXbatch shell strategy.

The strategies of fixed and login exist for host systems that are short on available free processes. In these two strategies, a single shell is exec'd, and that same shell is the shell that executes all of the commands in the batch request script.

The shell strategy configured for a particular CXbatch system can be determined by the qlimit(1) command.

-t process-id Signal process process-id when the job completes execution. The signal sent depends on how the job completed. If the job runs to normal completion, SIGTERM is sent. If the job is aborted while running, SIGUSR1 is sent. If the job is deleted before it starts executing, SIGUSR2 is sent.

-x Export all environment variables. When a batch request is submitted, the current values of the environment variables HOME, SHELL, PATH, USER, and MAIL are saved for later recreation when the batch request is spawned, as the respective environment variables QSUB_HOME, QSUB_SHELL, QSUB_PATH, QSUB_USER, and QSUB_MAIL. Unless the -x flag is specified, no other environment variables are exported from the originating host for the batch request. If the -x flag option is specified, all remaining environment variables whose names do not conflict with the automatically exported variables are also exported with the request. These additional environment variables are recreated under the same name when the batch request is spawned.

-y Append accounting data to the stdout output file if accounting is enabled for the queue in which the job runs. This data includes: queue, host, sequence number, remote host, submission time, start time, completion time, time spent executing in user mode, and time spent executing in the system.

-z Submit the batch request silently. If the request is submitted successfully, no messages are displayed indicating this fact. Error messages are, however, always displayed.

If the batch request is successfully submitted, and the -z flag has not been specified, the request-id of the request is displayed to the user. A request-id is always of the form seqno.hostname, where seqno refers to the sequence number assigned to the request by CXbatch, and hostname refers to the name of originating local machine. This identifier is used throughout CXbatch to uniquely identify the request, no matter where it is in the network.

The following events take place in the following order when a CXbatch batch request is spawned:

1. The process that will become the head of the process group for all processes comprising the batch request is created by CXbatch.
2. Resource limits are enforced.
3. The real and effective group-id of the process is set to the group-id as defined in the local password file for the request owner.
4. The real and effective user-id of the process is set to the real user-id of the batch request owner.
5. The user file creation mask is set to the value that the user had on the originating machine when the batch request was first submitted.
6. If the user explicitly specified a shell by use of the -s flag (discussed above), then that user-specified shell is chosen as the shell that will be used to execute the batch request script. Otherwise, a shell is chosen based upon the shell strategy as configured for the local CXbatch system. (See the earlier discussion of the -s flag for a description of the possible shell strategies that can be configured for a CXbatch system.)
7. The environment variables of HOME and SHELL, are set from the user's password file entry, as though the user had logged directly into the execution machine.

8. The environment string: ENVIRONMENT=BATCH is added to the environment so that shell scripts (and the user's .profile (Bourne shell) or .cshrc and .login (C-shell) scripts) can test for batch request execution when appropriate, and not (for example) perform any setting of terminal characteristics, because a batch request is not connected to an input terminal.

9. The environment variables of QSUB_WORKDIR, QSUB_HOST, QSUB_REQNAME, and QSUB_REQID are added to the environment. These environment variables equate to the obvious respective strings of the working directory at the time that the request was submitted, the name of the originating host, the name of the request, and the request request-id.

10. All of the remaining environment variables saved for recreation when the batch request is spawned are added at this point to the environment. When a batch request is initially submitted, the current values of the environment variables HOME, SHELL, PATH, USER, and MAIL are saved for later recreation when the batch request is spawned. When recreated however, these variables are added to the environment under the respective names QSUB_HOME, QSUB_SHELL, QSUB_PATH, QSUB_USER, and QSUB_MAIL to avoid the obvious conflict with the local version of these environment variables. Additionally, all environment variables exported from the originating host by the -x option are added to the environment at this time.

11. The current working directory is then set to the user's home directory on the execution machine, and the chosen shell is exec'd to execute the batch request script with the environment as constructed in the steps outlined above.

Unless the -l option is specified, the chosen shell is exec'd as a non-login shell and no start-up files (except the ~/.cshrc for a C-shell) are read. If the -l option is selected, the chosen shell is exec'd as though it were the login shell. If the Bourne shell is chosen to execute the script, /etc/profile and the user's .profile file are read. If the C-shell is chosen, /etc/login and the user's .cshrc and .login scripts are read and when the job exits, /etc/logout and the user's .logout script are read.

If the user did not specify a shell for the batch request, CXbatch chooses which shell is used to execute the shell script, based on the shell strategy as configured by the system administrator. (See the earlier discussion of the -s flag.)

In such a case, a free shell strategy instructs CXbatch to execute the login shell for the user (as configured in the password file). The login shell is in turn instructed to examine the shell script file and fork another shell of the appropriate type to interpret the shell script, behaving exactly as an interactive invocation of the script.

Otherwise no additional shell is spawned, and the chosen fixed or login shell sequentially executes the commands contained in the shell script file until completion of the batch request.

**QUEUE TYPES**

CXbatch supports three different queue types that serve to provide three very different functions. These three queue types are known as batch, pipe, and network.

The queue type of batch can only be used to execute CXbatch batch requests. Only CXbatch batch requests created by the qsub(1) command can be placed in a batch queue.

Queues of type pipe are used to send CXbatch requests to other pipe queues or to request destination queues of type batch. In general, pipe queues, in combination with network queues, act as the mechanism that CXbatch uses to transport batch requests to distant queues on remote machines. It is also legal for a pipe queue to transport requests to queues on the same machine.
When a pipe queue is defined, it is given a destination set that defines the set of possible destination queues for requests entered in that pipe queue. In this manner, it is possible for a batch request to pass through many pipe queues on its way to its ultimate destination, which must eventually be a queue of type batch.

Each pipe queue has an associated server. For each request handled by a pipe queue, the associated server is spawned which must select a queue destination for the request being handled, based upon the characteristics of the request and upon the characteristics of each queue in the destination set defined for the pipe queue.

Because a different server can be configured for each pipe queue, and batch queues can be endowed with the pipeonly attribute that will only admit requests queued via another pipe queue, it is possible for respective CXbatch installations to use pipe queues as a request class mechanism, placing requests that ask for different resource allocations in different queues, each of which can have different associated limits and priorities.

It is also completely possible for a pipe queue server, when handling a request, to discover that no destination queue will accept the request, for various reasons that can include insufficient resource limits to execute the request or a lack of a corresponding account or privilege for queuing at a remote queue. In such circumstances, the request is deleted, and the user is notified by mail (see mail(1)).

The queue type of network, as alluded to earlier, is implicitly used by pipe queues to pass CXbatch requests between machines and is also used to handle queued file transfer operations.

**QUEUE ACCESS**

CXbatch supports queue access restrictions. For each queue of queue type other than network, access may be either unrestricted or restricted. If access is unrestricted, any request may enter the queue. If access is restricted, a request can only enter the queue if the requester or the requester's login group has been given access to that queue (see qmgr(8)). Requests submitted by the superuser are an exception; they are always queued, even if the superuser has not explicitly been given access.

Use qstat(1) to determine who has access to a particular queue.

**LIMITS**

CXbatch supports many batch request resource limit types that can be applied to a batch request. The existence of configurable resource limits allows a CXbatch user to set resource limits within which his or her request must execute.

The syntax used to specify a limit-value for one of the limit-flags (-Ix), is quite flexible and describes values for three general limit categories. These three general categories respectively deal with time limits, priority (nice value) limits and file/memory size limits.

All the limit-flags expect a single limit-argument. If the limit-argument consists any whitespace which will cause the it to be passed to qsub as multiple tokens, it should be enclosed within double quotes or otherwise escaped such that is is passed a a single, character-string token. The optional warn-limit should also be included as part of the same token. This also applies to limit-arguments associated with limit-flags embedded within the batch request script file.

For finite CPU time limits, the limit-value is expressed in the reasonably obvious format:

```
[[hours :] minutes :] seconds [,milliseconds]
```

Whitespace can appear anywhere between the principal tokens, with the exception that no whitespace can appear around the decimal point. **NOTE:** The milliseconds value may be ignored if the system on which the request is run does not support such granularity.
Example time limit-values are:

center, tab(;) 11 1234 : 58 : 21.29:-- 1234 hrs 58 mins 21.290 secs 12345:-- 12345 seconds 121.1:-- 121.100

Priority limits are expressed as a small, signed integer in the range acceptable for nice values on the execution machine. In general, increasingly negative nice values cause the relative execution priority of a process to increase, while increasingly positive nice values causes the relative priority to decrease. Because different UNIX implementations often support different finite ranges of nice values, CXbatch allows the specification of nice values that can eventually turn out to be outside the limits for the UNIX implementation running at the execution machine. In such cases, CXbatch simply binds the specified nice values limit to within the necessary range as appropriate.

For the finite size limits the acceptable syntax is:

\[ \text{fraction \ [units]} \]

or

\[ \text{integer \ [fraction] \ [units]} \]

where the integer and fraction tokens represent strings of up to eight decimal digits, denoting the obvious values. In both cases, the units of allocation may also be specified as one of the case insensitive strings:

center, tab(;) 11 1. b:-- bytes w:-- words kb:-- kilobytes (2\^10 bytes) kw:-- kilowords (2\^10 words) mb:-- megabytes (2\^20 bytes) mw:-- megawords (2\^20 words) gb:-- gigabytes (2\^30 bytes) gw:-- gigawords (2\^30 words)

In the absence of any units specification, the units of bytes are assumed.

For all limit types with the exception of the nice limit-value (-ln), it is possible to state that no limit should be applied. This is done by specifying a limit-value of "unlimited" or any initial substring thereof. Whenever an infinite limit-value is specified for a particular resource type, the batch request operates as though no explicit limits have been placed upon the corresponding resource, other than by the limitations of the physical hardware involved.

The complications caused by batch request resource limits first show up when queuing a batch request in a batch queue. This operation is described in the following paragraphs.

If a batch request specifies a limit that cannot be enforced by the underlying UNIX implementation, the limit is simply ignored, and the batch request operates as though there were no limit (other than the obvious physical maximums) placed upon that resource type. (See the qlimit(1) command to find out what limits are supported by a given machine.)

For each remaining finite limit that can be supported by the underlying UNIX implementation that is not a CPU time-limit or UNIX execution-time nice-value-limit, the limit-value is internally converted to the units of bytes or words, whichever is more appropriate for the underlying machine architecture.

As an example, a per-process memory size limit value of 321 megabytes would be interpreted as 321 x 2\^20 bytes, provided that the underlying machine architecture was capable of directly addressing single bytes. Thus the original limit coefficient of 321 would become 321 x 2\^20. On a machine that was only capable of addressing words, the appropriate conversion of 321 x 2\^20 bytes / #of-bytes-per-word would be performed.
If the result of such a conversion would cause overflow when the coefficient was represented as a *signed-long integer* on the supporting hardware, the coefficient is replaced with the coefficient of \(2^N-1\), where \(N\) is equal to the number of bits of precision in a signed long integer. For typical 32-bit machines, this *default extreme limit* would therefore be \(2^{31}-1\) bytes. For word addressable machines in the supercomputer class supporting 64-bit long integers, the *default extreme limit* would be \(2^{63}-1\) words.

Lastly, some implementations of UNIX reserve coefficients of the form: \(2^N-1\) as synonymous with infinity, meaning no limit is to be applied. For such UNIX implementations, CXbatch further decrements the *default extreme limit* so as not to imply infinity.

The identical internal conversion process as described in the preceding paragraphs is also performed for each *finite limit-value* configured for a particular batch queue using the `qmgr(8)` program.

After all of the applicable *limit-values* have been converted as described above, each resulting *limit-value* is then compared against the corresponding *limit-value* as configured for the destination batch queue. If, for every type of limit, the batch queue *limit-value* is *greater than* or *equal to* the corresponding batch request *limit-value*, the request can be successfully queued, provided that no other anomalous conditions occur. For request *infinity limit-values*, the corresponding queue *limit-value* must also be configured as infinity.

These resource limit checks are performed irrespective of the batch request arrival mechanism, either by a direct use of the `qsub(1)` command or by the indirect placement of a batch request into a batch queue via a *pipe* queue. It is impossible for a batch request to be queued in a batch queue if any of these resource limit checks fail.

Finally, if a request fails to specify a *limit-value* for a resource limit type that is supported on the execution machine, the corresponding *limit-value* configured for the destination queue becomes the *limit-value* for the unspecified request limit.

Upon the successful queuing of a request in a batch queue, the set of limits under which the request will execute is frozen and will not be modified by subsequent `qmgr(8)` commands that alter the limits of the containing batch queue.

**CAVEATS**

When a batch request is spawned, a new *process-group* is established such that all processes of the request exist in the same *process-group*. If the `qdel(1)` command is used to send a signal to a batch request, the signal is sent to all processes of the request in the created *process-group*. However, should one or more processes of the request choose to successfully execute a `setpgid(2)` system call, such processes will not receive any signals sent by the `qdel(1)` command. This can lead to "rogue" requests whose constituent processes must be killed by other means such as the `kill(1)` command.

It is extremely wise for all processes of a CXbatch request to catch any SIGTERM signals. By default, the receipt of a SIGTERM signal causes the receiving process to die. CXbatch sends a SIGTERM signal to all processes in the established *process-group* for a batch request as a notification that the request should be prepared to be killed, either because of an `abort queue` command issued by an operator using the `qmgr(8)` program, or because it is necessary to shutdown CXbatch and all running requests as part of a general shutdown procedure of the local host.

It must be understood that the spawned *shell* ignores SIGTERM signals. If the current immediate child of the shell does not ignore or catch SIGTERM signals, it will be killed by the receipt of such, and the shell will go on to execute the next command from the script (if there is one). In any case, the shell will not be killed by the SIGTERM signal, though the executing command will have been killed.

After receiving a SIGTERM signal delivered from CXbatch, a process of a batch request typically has sixty seconds to get its "house in order" before receiving a SIGKILL signal (though the sixty
second duration can be changed by the operator).

All batch requests terminated because of an operator CXbatch shutdown request that did not specify the \texttt{-nr} flag are considered restartable by CXbatch and are requeued (provided that the batch request shell process is still present at the time of the SIGKILL signal broadcast as discussed above), so that when CXbatch is rebooted, such batch requests will be respawned to continue execution. It is, however, up to the user to make the request restartable by the appropriate programming techniques. CXbatch simply spawns the request again as though it were being spawned for the first time.

Upon completion of a batch request, a mail message can be sent to the submitter (see the discussion of the \texttt{-me} flag above). In many instances, the completion code of the spawned Bourne or C-Shell is displayed. This is the value returned by the shell through the \texttt{exit(2)} system call.

Lastly, there is no good way to echo commands executed by unmodified versions of the Bourne and C shells. While the Bourne and C shells can be spawned in such a fashion as to echo the commands they execute, it is often very difficult to tell an echoed command from genuine output produced by the batch request.

Thus, one of the better ways to write the shell script for a batch request is to place appropriate lines in the shell script of the form:

\begin{verbatim}
  echo "explanatory-message"
\end{verbatim}

where the echoed message should be a meaningful message chosen by the user.

**DIAGNOSTICS**

\texttt{qsub} returns an exit status describing what it did. If there were no errors, the exit status is zero. If a fatal error occurs and the request is not submitted (e.g., a syntax error), the exit status is one of the codes defined in \texttt{<sysexits.h>}, or one if none of the \texttt{<sysexits.h>} codes are appropriate.

\begin{itemize}
  \item **EX_USAGE** The command was used incorrectly, e.g., with the wrong number of arguments, a bad flag, a bad syntax in a parameter.
  \item **EX_OSFILE** Some batch system file does not exist, cannot be opened, or has an error.
  \item **EX_TEMPFAIL** Temporary failure; retry the request at a later time.
  \item **EX_NOPERM** You did not have sufficient permission to perform the operation.
  \item **EX_NOINPUT** The script file does not exist or is not readable.
\end{itemize}

**NOTES**

CXbatch is an optional product; for more information, contact your CONVEX sales representative.
NAME
batch-acct – CXbatch accounting file

DESCRIPTION
Batch accounting can be performed by CXbatch on a per queue basis. Batch accounting is enabled with the qmgr command `set accounting`. The accounting log file is specified with `set acc_logfile`. By default, accounting is off and the log file is `/dev/null`.

CONVEX provides qsa(8) for processing and reporting the batch accounting data. The log file is in binary format, and its structure is described in the C include file `/usr/include/batch-acct.h`.

FILES
/usr/include/batch-acct.h

SEE ALSO
qmgr(8), qsa(8)
NAME
nqsdaemon, netdaemon, logdaemon - CXbatch daemons

SYNOPSIS
/usr/lib/nqs/nqsdaemon

DESCRIPTION
nqsdaemon, netdaemon, and logdaemon are CXbatch daemons that are normally started at boot
time from the /etc/rc.local file. nqsdaemon automatically starts netdaemon and logdaemon.
nqsdaemon handles all local transactions, including submits, deletes, job scheduling, and system
configuration. netdaemon handles all possibly remote transactions, including submits and file
staging. nqsdaemon and netdaemon contact logdaemon when they need to print an error message.
logdaemon sends the message to syslogd and notifies the batch managers if the error is fatal. See
qmgr(8) for more information on defining CXbatch managers.

SEE ALSO
qdel(1), qjlist(1), qlimit(1), qstat(1), qsub(1), pipeclient(8), qmapmgr(8), qmgr(8), syslogd(8).

FILES
/usr/lib/nqs - directory containing CXbatch daemons
/etc/nmap - directory that contains network database

NOTES
CXbatch is an optional product; for more information, contact your CONVEX sales representa-
tive.
NAME
  pipeclient, pipeldav - CXbatch pipe clients

SYNOPSIS
  /usr/lib/nqs/pipeclient
  /usr/lib/nqs/pipeldav [ -w weight ] [ host scale ... ]

DESCRIPTION
  CXbatch supports pipe queues that are responsible for routing and delivering requests to other
  (possibly remote) queue destinations. With each pipe queue, there is an associated pipe client that
  is spawned to handle each request released from the queue for routing and delivery. When a pipe
  client is spawned, it is given complete freedom to route the request to any of the destinations in
  its destination set. CONVEX supplies two pipe clients, pipeclient and pipeldav, that use different
  methods for determining which destination should get the request.

  The standard pipe client, pipeclient, routes the request to the first destination that will accept the
  request. Destinations may reject the request due to queue limit violations, lack of account
  authorization, and many other reasons.

  pipeldav sorts the destination list by load factor, and tries destinations with low load factors first.
  The load factor is calculated as follows:

  \[
  \text{load factor} = \frac{\text{load avg} + \text{queue length} \cdot \text{weight}}{\text{scale}}
  \]

  The load average is the current system load average on the destination machine. The queue
  length is the number of requests in the destination queue. The weight and scale are specified on
  the pipeldav command line and are the job weight and host scale factor.

  See qmgr(8) for more information on configuring pipe queues.

RESTRICTIONS
  The pipe client pipeldav gets load average information from rstatd. As a result, pipeldav is limi-
  ted to load balancing over machines running rstatd.

  tive.
NAME
qmapmgr – configures the CONVEX Extended Batch System (CXbatch) network

SYNOPSIS
qmapmgr

DESCRIPTION
The qmapmgr command builds the network database that CXbatch uses to direct files and messages. CXbatch needs this network database file no matter how simple the machine configuration.

This network database consists of three primary elements:

- **mid** A machine ID number that is unique in the CXbatch network being configured. CXbatch uses this mid to identify a specific machine. A maximum value of \((2^{31})-1\) is permissible.
- **principle name** A machine name that is unique in the CXbatch network being configured.
- **alias** Names, other than the principle name, of machines in the network. Aliases are known only to the local CXbatch host.

To gain entry to the CXbatch network mapping manager, enter the qmapmgr command. You can enter any of the commands described below at the prompt. You can leave qmapmgr using the exit or quit commands.

COMMANDS
You can abbreviate commands to their minimum unambiguous length. For example, you can abbreviate change name to ch n. However, c n is not acceptable because the command create exists. You should enter all commands on a single command line. You can enter the following commands at the prompt.

- **add mid mid principal name**
  Adds a new machine to the configuration with the specified mid and principle name.

- **add name alias mid**
  Adds an alias for the machine with the specified mid.

- **change name mid principle name**
  Changes the principle name of the machine with the specified mid.

- **create**
  Creates a new network configuration database file.

- **delete mid mid**
  Removes the machine with the specified mid from the configuration database.

- **delete name alias**
  Deletes the given alias from the configuration database.

- **exit**
  Leaves the qmapmgr program.

- **get mid name**
  Displays the id of the machine with the specified principle name or alias.

- **get name mid**
  Displays the principle name of the machine with the specified mid.

- **help**
  Displays the available commands.
quit
Leaves the qmapmgr program.

show
Displays all mid entries with their corresponding principle name and aliases.

SEE ALSO
qmgr(8)

FILES
/etc/nmap - directory that contains network database

NOTES
CXbatch is an optional product; for more information, contact your CONVEX sales representative.
NAME
qmgr - CXbatch queue manager program

SYNOPSIS
qmgr [ command [ options ] ]

DESCRIPTION
qmgr is the primary utility used to configure, administer and operate the CXbatch system. qmgr recognizes three classes of users: managers, operators, and users. The superuser is a manager by default. All other managers and operators are assigned using qmgr. Managers can use any of the qmgr commands. Operators can use a subset of the commands. Users who are not granted manager or operator privileges can use only a few of the qmgr commands to display status information and manipulate their own requests.

The CXbatch system is made up of batch and pipe queues that transport and run batch requests. A batch queue holds requests for scheduled, perhaps delayed, processing. A pipe queue is a queue that can pass queued requests on to other pipe queues or batch queues. A batch request is a set of commands, or a shell script, that is to be run non-interactively with the results being returned to the user. The running of the request is handled by the CXbatch system rather than directly by the user.

qmgr can be invoked to run a single command given as the command line argument or, if no argument is given, as a command interpreter. As an interpreter, commands will be repeatedly prompted for and executed. The qmgr command set is extensive and will be discussed in functional groups below. Command keywords are case insensitive and can be abbreviated to their shortest unique substring. This is indicated in the command descriptions below by capitalizing the require substring. For example, when using the exit command, you must type at least 'ex' to distinguish it from the enable command. Thus the description for this command is:

EXIT
Exit from the CXbatch manager subsystem.

INFORMATIONAL COMMANDS
The following commands return information about qmgr commands, CXbatch parameters and queue configuration. They are available to all users.

HELP [ command ]
Get help information. HELP without an argument displays information about what commands are available. HELP with an argument displays information about that command. The command may be partially specified as long as it is unique. A more complete help request yields more detailed information.

The HELP command provides information that is often more extensive than the command descriptions in this manual page! Use it.

SHOW All
Display the standard amount of information about "limits supported", managers, parameters, and queues. See below.

SHOW Limits_supported
Display the list of CXbatch resource limit types that are meaningful on this machine. Note that users may request resource limits that are not meaningful on the machine where qsub(1) is invoked. If the request is to be executed on a remote machine where the limit is meaningful, then CXbatch honors it. Otherwise the unsupported limit is simply ignored.

SHOW Long Queues [ queue [ user ] ]
Display in long format the status of all CXbatch queues on this host. If a queue is
specified, output is limited to that queue. If a user is specified, output downplays any requests not belonging to that user.

SHOW Managers
Display the list of authorized CXbatch managers.

SHOW Parameters
Display the general CXbatch parameters.

SHOW Queues [ queue [ user ] ]
Display the status of all CXbatch queues on this host. If a queue is specified, output is limited to that queue. If a user is specified, output downplays any requests not belonging to that user.

QUEUE MANAGEMENT
The following commands are used to define batch and pipe queues. They can be used only by CXbatch managers. For more information on the different types of queues, see the QUEUE TYPES section below.

CREATE Batch_queue queue PRiority = n [ Plpeonly ]
[ Run_limit = n ] [ Import_dir = {Yes, No, Available} ]
[ Share_policy Fixed = user ] [ Share_policy User ]
Define a batch queue named queue with inter-queue priority n (0..63). If Plpeonly is specified, then requests may enter this queue only if their source is a pipe queue. The specification of a Run_limit sets a ceiling on the maximum number of requests allowed to run in the batch queue at any given time. The default Run_limit is one.

The specification of the Import_dir attribute determines the availability of the user's current working directory to a request at runtime. See the SET Import_dir command for more information.

The specification of a Share_policy affects how the CPU usage of jobs running in this queue is charged. See the SET SHARE_policy Fixed and the SET SHARE_policy User commands for more information.

CREATE Pipe_queue queue PRiority = n Server = ( server )
[ Destination = destination ]
[ Destination = ( destination , destination ... ) ]
[ Plpeonly ] [ Run_limit = n ]
Define a pipe queue named queue with inter-queue priority n (0..63) and associate it with a server. This is done by specifying an absolute path name to the program binary (server) and any arguments required by the program. After Destination appears a list of one or more destination queues that requests from this pipe queue may be sent to. If Plpeonly is specified, then requests may enter this queue only if their source is a pipe queue. Run_limit sets a ceiling on the maximum number of requests allowed to run in the pipe queue at any given time. The default Run_limit is one.

ADD Alias alias queue
Add the specified queue alias to "queue". A queue alias is an alternate name for a queue; any CXbatch command that requires a queue name will also work with an alias.

DELETE Alias alias
Delete the specified queue "alias". A queue alias is an alternate name for a queue; any CXbatch command that requires a queue name will also work with an alias.

DELETE Queue queue
The queue is deleted. To delete a queue, no requests may be present in the queue, and
the queue must be disabled. (See "Disable Queue" below.)

**SEt DESCription = (description) queue**

Change the description of the named CXbatch queue.

**SEt PRiority = priority queue**

Specify the inter-queue priority of a queue.

**QUEUE ACCESS**

CXbatch supports queue access restrictions. For each queue access may be either *unrestricted* or *restricted*. If access is *unrestricted*, any request may enter the queue. If access is *restricted*, a request can only enter the queue if the requester or the requester's login group has been given access. Requests submitted by the superuser are an exception; they are always queued, even if the superuser has not explicitly been given access.

The following commands are used to grant access to queues. They can be used only by CXbatch managers.

In the **ADd** and **DEiete** commands below a *group* or *user* can be specified in one of two ways: *name* or [*id*]. (The square brackets are literal characters used to indicate a gid or uid.)

**ADd Groups = group queue**

**ADd Groups = (group [ , group ... ] ) queue**

The specified group(s) are added to the access list for *queue*.

**ADd Users = user queue**

**ADd Users = (user [ , user ... ] ) queue**

The specified user(s) are added to the access list for *queue*.

**DEiete Groups = group queue**

**DEiete Groups = (group [ , group ... ] ) queue**

The specified group(s) are deleted from the access list for *queue*.

**DEiete Users = user queue**

**DEiete Users = (user [ , user ... ] ) queue**

The specified user(s) are deleted from the access list for *queue*.

**SEt NO_Access queue**

Specify that no one can place requests in *queue*.

**SEt Unrestricted_access queue**

Specify that no requests will be turned away from *queue* on the grounds of queue access restrictions.

**BATCH QUEUE CONFIGURATION**

The following commands are used to set the operating parameters for batch queues. They can only be used by CXbatch managers.

**SEt ACCOunting = {OF/, ON} queue**

Turn accounting on/off for a CXbatch batch queue. The queue named as a parameter of the command must already exist.

**SEt ACTivity_id_offset = offset queue**

Set the activity ID offset for a CXbatch batch queue. The queue named as a parameter of the command must already exist.

**SEt CHKpointable = {Yes, No, Available} queue**

Sets the status of the per-queue checkpoint resource. The queue must exist. The queue's
checkpoint resource value and the request's flags are used to determine if a request may be checkpointed.

If the checkpoint attribute is set to "Yes", then any request submitted to this queue will be checkpointed at CXbatch shutdown and may be checkpointed by the request owner or CXbatch operator, unless it explicitly requested not to be checkpointed. If this attribute is set to "Available", the request is checkpointable only if it specifically asked to be checkpointed. Requests in a queue with the checkpoint attribute set to "No" cannot be checkpointed by CXbatch.

**SEt Import_dir = \{Yes,No,Available\} queue**

Changes the Import_dir attribute for a queue. The queue must already exist. If the Import_dir attribute is set to Yes, any job submitted to this queue is run in the user's current working directory, unless the job specifically requests not to be imported. If the Import_dir attribute is set to Available, only jobs that specifically request to be imported are imported. If it is set to No, jobs are run in the home directory. When importing, if a job is executed on a remote machine, CXbatch tries to access the local directory using NFS mounts. **NOTE**: CXbatch will make temporary NFS mounts into the /tmp filesystem. Care should be taken that any automatic clean-up operations on the /tmp filesystem do not traverse NFS mount points.

**SEt MAXimum Request_priority = priority queue**

Set a limit on request priorities on a per queue basis. Requests queued with a priority higher than the queue's maximum will have their priority lowered to the maximum.

**BATCH QUEUE LIMITS**

The following commands are used to set the limits batch queues impose on their requests. Every batch queue on the local host have each of the following limits associated with it at all times. If a request already in the queue has asked for more than a new limit, it is given a grandfather clause and allowed to retain its original limits. A request which specifies a particular limit may only enter a batch queue if the queue's corresponding limit is greater than or equal to the request's limit. See the section on LIMITS below for more information on the syntax on the various limit arguments. These commands can only be used by CXbatch managers.

**SEt COREfile_limit = \( limit \) queue**

Set a per-process maximum core file size limit for a batch queue against which the per-process maximum core file size limit for a request may be compared.

**SEt Data_limit = \( limit \) queue**

Set a per-process maximum data segment size limit for a batch queue against which the per-process maximum data segment size limit for a request may be compared.

**SEt NICE_value_limit = nice-value queue**

Set the UNIX nice-value limit for a batch queue, against which the nice value for a request may be compared. A request specifying a nice-value may only enter a batch queue if the queue's nice value is numerically less than (more willing to allow access to the CPU) or equal to the request's nice value. nice-value is an integer preceded by an optional negative sign.

**SEt PER_Process Cpu_limit = \( limit \) queue**

Set a per-process maximum CPU time limit for a batch queue against which the per-process maximum CPU time limit for a request may be compared.

**SEt PER_Process Permfile_limit = \( limit \) queue**

Set a per-process maximum permanent file size limit for a batch queue against which the
per-process maximum permanent file size limit for a request may be compared.

SET STACK_LIMIT = (limit) queue

Set a per-process maximum stack segment size limit for a batch queue against which the per-process maximum stack segment size limit for a request may be compared.

SET WORKING_SET_LIMIT = (limit) queue

Set a per-process maximum working set size limit for a batch queue against which the per-process maximum working set size limit for a request may be compared.

PIPE QUEUE CONFIGURATION

The following commands are used to set the operating parameters for pipe queues. They are only available to CXbatch managers.

ADD DESTINATION = destination queue
ADD DESTINATION = (destination [ , destination ... ] ) queue

The specified destination(s) are added as valid destinations for a pipe queue named "queue".

DELETE DESTINATION = destination queue
DELETE DESTINATION = (destination [ , destination ... ] ) queue

Delete the mappings from the pipe queue queue to the destination queues. All requests from the named queue being transferred to a deleted destination complete normally. If all destinations for a pipe queue are deleted in this manner, the pipe queue is effectively stopped.

SET DESTINATION = destination queue
SET DESTINATION = (destination [ , destination ... ] ) queue

Associate one or more destination queues with a particular pipe queue.

SET PIPE_CLIENT = (client) queue

Associate a pipe client with a pipe queue. client should consist of the absolute path name to the program binary followed by any arguments required by the program.

DESIGNATING MANAGERS AND OPERATORS

The following commands are used to specify CXbatch managers and operators. They can only be used by CXbatch managers.

A manager specification consists of an account name specification, followed by a colon, followed by either the letter m or the letter o. There are four ways to specify an account name:

- local_account_name
- [local_user_id]
- [remote_user_id]@remote_machine_name
- [remote_user_id]@[remote_machine_mid]

(The square brackets are literal characters used to indicate a uid or mid.) If the account name specification is followed by :m, the account is designated as a CXbatch manager account, capable of using all qmgr commands. If the account name specification is followed by :o, the account is designated as a CXbatch operator account, capable of only using those commands appropriate for a CXbatch operator. The root account always has full privileges.

ADD MANAGERS manager ...

The specified manager(s) are added to the list of authorized CXbatch managers with privileges as specified.

DELETE MANAGERS manager ...

The specified manager(s) are deleted from the list of authorized CXbatch managers.
**SEt MANagers manager**

The list of authorized CXbatch managers is set to the specified manager(s).

**GENERAL CXBATCH MANAGEMENT**

The following commands are used to set the general operating parameters of CXbatch. Only CXbatch managers can use these commands.

**SEt ACC_log:file filename**

Change the file being used for CXbatch batch accounting.

**SEt Aid_mask = mask**

Set the activity ID mask. Generally, this mask is the same as the spacing between aids in `/etc/activities`. The following equation is used to determine the activity ID of the CXbatch job:

\[
job\_aid = submitter\_aid - (submitter\_aid \% aid\_mask) + queue\_aid\_offset
\]

where `%` is the modulus (remainder) function.

**Warning**: As shipped, the aid mask is one. When the mask is one, the above equation simplifies to \(job\_aid = submitter\_aid + queue\_aid\_offset\). In this case, if a CXbatch job submits another CXbatch job, the second job has an activity ID of 
\(submitter\_aid + queue\_1\_aid\_offset + queue\_2\_aid\_offset\). This is generally not desirable! Setting the activity ID mask to the spacing in `/etc/activities` prevents this from happening.

**SEt CHEckpoint_directory directory**

Specify the pathname of the checkpoint directory. All checkpoint files created by CXbatch after this command is issued will be placed in directory. Existing checkpoint files will not be moved. The directory must exist and be a valid directory.

**SEt DEBug level**

Set the debug level. The following values are valid:

- 0 No debug
- 1 Minimum debug
- 2 Maximum debug

**SEt DEFault Batch_request Priority priority**

Set the default intra-batch-queue priority. This is not the UNIX execution time priority. This is the priority used if the user does not specify an intra-queue priority parameter on the `qsub(1)` command.

**SEt DEFault Batch_request Queue queue**

Set the default batch queue. This is the queue used if the user does not specify a queue parameter on the `qsub(1)` command.

**SEt DEFault DEStination_retry Time retry_time**

Set the default number of hours that can elapse during which time a pipe queue destination can be unreachable, before being marked as completely failed.

**SEt DEFault DEStination_retry Wait interval**

Set the default number of minutes to wait before retrying a pipe queue destination that was unreachable at the time of the last attempt.

**SEt Global Per_user Run_limit = run-limit**

Set the global per-user run-limit of the local system. The global per-user run-limit is the maximum number of requests that any given user can have running on the local system.
at any given time. A global per-user run-limit of 0 turns off the enforcement of this limit.

SET MAIL userid
Specify the userid used to send CXbatch mail.

SET NO_Default Batch_request Queue
Indicate that there is to be no default batch request queue.

SET SHELL_strategy Fixed = (shell)
Specify that shell should be used to execute all batch requests. shell must be the absolute path name of a command interpreter. (See the SHELL STRATEGIES section below for more information.)

SET SHELL_strategy Free
Specify that the free shell strategy should be used to execute all batch requests. The free shell strategy duplicates the shell choice that would have been made if the batch request script had been executed interactively. Under this strategy, the user's login shell is allowed to determine the shell to be used to execute the batch request. The user's login shell is the shell named within the user's entry in the password file (see passwd(4)). (See the SHELL STRATEGIES section below for more information.)

SET SHELL_strategy Login
Specify that the login shell strategy should be used to execute all batch requests. Under the login shell strategy, the user's login shell is used to execute the batch request. The login shell is the shell named in the password file (see passwd(4)). (See the SHELL STRATEGIES section below for more information.)

GENERAL CXBATCH OPERATION
The following commands are used for starting and shutting down CXbatch. They can be used by CXbatch managers or operators.

SHUTDOWN [ Force | [ seconds ]
Shutdown CXbatch on the local host.

Each running checkpointable batch request is checkpointed, and, if the checkpoint succeeds, terminated. Successfully checkpointed requests will be restarted from their checkpointed state when CXbatch is rebooted.

After running requests are checkpointed, a SIGTERM signal is sent to each process of each request presently running. After the specified number of seconds of real time have elapsed, a SIGKILL signal is sent to all remaining processes for each request. If a seconds value is not specified, the delay is sixty seconds. Unlike ABORT QUEUE, SHUTDOWN requeues all of the requests it kills, provided that the initial SIGTERM signal is caught or ignored by the running request.

When the optional force keyword is present CXbatch ignores any checkpoint errors incurred during the shutdown.

START CXbatch
Start CXbatch on the local host. This command will fail if CXbatch is currently running on the local host.

QUEUE OPERATION
The following commands are used in operating queues in CXbatch. They can be used by CXbatch managers or operators.

ABORT QUEUE queue [ seconds ]
All requests in the named queue that are currently running are aborted as follows. A SIGTERM signal is sent to each process of each request presently running in the named queue. After the specified number of seconds of real time have elapsed, a SIGKILL signal is sent to all remaining processes for each request running in the named queue. If a seconds value is not specified, the delay is sixty seconds. All requests aborted by this command are deleted, and all output files associated with the requests are returned to the appropriate destination.

DISABLE QUEUE

Prevent any more requests from being placed in this queue.

ENABLE QUEUE

If the queue is already enabled, this command has no effect. Otherwise, the queue is enabled to accept new requests.

MOVE QUEUE

Move all requests currently in queue1 to queue2. The request is moved regardless of any queue limit violations, access restrictions, or attribute violations.

PURGE QUEUE

All queued requests are dropped from the queue and are irretrievably lost. Running requests in the queue are allowed to complete.

START QUEUE

If the queue is already started, then nothing happens. Otherwise, the queue is started and requests in the queue are eligible for selection.

STOP QUEUE

Any requests in the queue that are currently running are allowed to complete. All other requests are "frozen" in the queue. New requests can still be submitted to the queue, but are "frozen" like the other requests in the queue.

QUEUE OPERATING PARAMETERS

The following commands are used to set the operating parameters of CXbatch queues. They can be used by CXbatch managers or operators.

SET PER_USER_RUN_LIMIT = run-limit queue

Change the per-user run-limit of a CXbatch batch queue. The per-user run-limit determines the maximum number of requests that any given user can have running in the queue at any given time. A per-user run-limit of 0 turns off the enforcement of this limit.

SET RUN_LIMIT = run-limit queue

Change the run-limit of a CXbatch batch or pipe queue. The run-limit determines the maximum number of requests that are allowed to run in the queue at any given time.

SET SHARE_POLICY Fixed = user queue

Change the share-policy of a CXbatch batch queue. A queue with a fixed share policy will charge the CPU usage of jobs run in that queue to account. There are two ways to specify a user: username or [id]. (The square brackets are literal characters used to indicate a uid.)

SET SHARE_POLICY User queue

Change the share-policy of a CXbatch batch queue. A queue with a user share policy will charge the CPU usage of jobs run in that queue to the account from which the job was submitted.
REQUEST OPERATIONS

The following commands operate on CXbatch requests. They can only be executed by CXbatch managers or operators.

**MOVe Request** requestid ... queue

Move the request(s) named by the requestid(s) to the named queue. The request is moved regardless of any queue limit violations, access restrictions, or attribute violations.

**RESume Request** requestid ...

Resume execution of suspended requests. Resumed requests start out in the *queued* state. Once the resumed request is about to enter the *running* state, it will be restarted from its checkpointed state instead of being re-run in its entirety.

**RUUn Request** requestid ...

Force the request(s) named by the requestid(s) to begin executing immediately. If running the request would exceed the current run limit of the queue, then the queue's run limit will be increased by one until the request finishes executing.

**SUspend Request** requestid ...

Temporarily freeze execution of the named requests. The requests are checkpointed and terminated. Of course, a request that fails to checkpoint will continue to execute. Only checkpointable requests may be suspended in this manner.

USER REQUEST OPERATIONS

The following commands operate on CXbatch requests. These commands may be used by non-privileged user in dealing with their own requests. Otherwise, they are limited to use by CXbatch managers or operators.

**CHKpnt Request** requestid ...

Checkpoint the request(s) named by the requestid(s). The state of the named batch request(s) is saved into a set of checkpoint files stored in the checkpoint directory.

**DElete Request** requestid ...

Delete the request(s) named by the requestid(s). This command can delete both running and non-running requests. If a request is running, then all processes of the request are sent a SIGKILL signal.

**HOLd Request** requestid ...

Makes the specified request(s), named by requestid(s), ineligible for running. The request(s) must be in the *queued* state prior to being held. The **RELease Request** command removes the effect of hold.

If a request is held by an operator, only an operator can release it.

**MODify Request** field = value requestid ...

Change the field of the request(s) specified by requestid(s) to be value.

The legal values for field are:

- **Priority** - change the intra-queue request priority. A user can only decrease a request's priority, *operator* privileges are required to raise a request's priority.

**MOVe My_request requestid ... queue**

Move your request(s) named by the requestid(s) to the named queue. The request is not moved if any queue limits, access restrictions, or attributes would have prevented the request from being submitted to the new queue.

**RELease Request** requestid ...

Makes the specified request(s), named by requestid(s), eligible for running. The request(s)
must be in the holding state prior to being released.

**QUEUE TYPES**

CXbatch supports two different queue types that provide two very different functions. These two queue types are known as "batch" and "pipe".

The queue type of "batch" can only be used to execute CXbatch batch requests. Only CXbatch batch requests created by the `qsub(1)` command can be placed in a `batch` queue.

Queues of type "pipe" are used to send CXbatch requests to other "pipe" queues or `batch` queues. In general, "pipe" queues act as the mechanism that CXbatch uses to transport "batch" requests to distant queues on other remote machines. It is also perfectly legal for a "pipe" queue to transport requests to queues on the same machine.

When a "pipe" queue is defined, it is given a destination set, that defines the set of possible destination queues for requests entered in that `pipe` queue. In this manner, it is possible for a "batch" request to pass through many pipe queues on its way to its ultimate destination, that must eventually be a queue of type "batch."

Each `pipe` queue has an associated server. For each request handled by a `pipe` queue, the associated server is spawned which selects a queue destination for the request being handled, based upon the characteristics of the request and upon the characteristics of each queue in the destination set defined for the pipe queue.

Because a different server can be configured for each `pipe` queue, and "batch" queues can be endowed with the "pipeonly" attribute that will only admit requests queued via another `pipe` queue, it is possible for respective CXbatch installations to use `pipe` queues as a request class mechanism, placing requests that ask for different resource allocations in different queues, each of which can have different associated limits and priorities.

It is also completely possible for a pipe client (pipe queue server), when handling a request, to discover that no destination queue will accept the request, for various reasons that can include insufficient resource limits to execute the request or a lack of a corresponding account or privilege for queuing at a remote queue. In such circumstances, the request is deleted, and the user is notified by mail (see `mail(1)`).

**SHELL STRATEGIES**

The execution of a batch request requires the creation of a shell process to interpret the shell script that defines the batch request. On many UNIX systems, there is more than one shell available (e.g., `/bin/csh`, `/bin/ksh`, `/bin/sh`). To deal with this problem, CXbatch allows a shell path name to be specified when a batch request is first submitted (`qsub` option `-s`).

If no particular shell is specified for the execution of the request, CXbatch must have some other means of deciding which shell to use when spawning the request. The solution to this dilemma has been to equip CXbatch with a batch request shell strategy that can be configured as necessary by the local system administrators.

The batch request shell strategy determines the shell to be used when executing a batch request on the local host that fails to identify any specific shell for its execution. Three such shell strategies can be configured for CXbatch, and they are known by the names of `fixed`, `free`, and `login`.

A shell strategy of `fixed` causes the request to be run by the `fixed shell`, the path name of which is configured by the system administrator. Thus, a particular CXbatch installation may be configured with a `fixed` shell strategy where the default shell used to execute all batch requests is defined as the Bourne shell.

A shell strategy of `free` causes the user's login shell (as defined in the password file), to be executed. This shell is, in turn, given a path name to the batch request shell script, and it is the user's login shell that actually decides which shell should be used to interpret the script. The `free` shell strategy therefore runs the batch request script exactly as would an interactive invocation of the script and is the default CXbatch shell strategy.
The third shell strategy of *login* causes the user's login shell (as defined in the password file) to be the default shell used to interpret the batch request shell script.

The strategies of *fixed* and *login* exist for host systems that are short on available free processes. In these two strategies, a single shell is executed, and that same shell is the shell that executes all of the commands in the batch request script (barring shell exec operations in any user startup files: .profile, .login, .cshrc).

The shell strategy as configured for any particular host can always be determined by the CXbatch *qlimit* command.

**LIMITS**

CXbatch supports many batch request resource limit types that can be applied to a CXbatch batch queue. The configurability of these limits allows a CXbatch manager to set batch queue-specific resource limits that all batch requests in the queue must adhere to.

The syntax of a *limit* in commands of the form **SEt Some_limit = ( limit ) queue** is quite flexible.

For *finite* CPU time limits, the acceptable syntax is as follows:

```
[[hours :] minutes :] seconds [.milliseconds]
```

Whitespace can appear anywhere between the principal tokens, with the exception that no whitespace can appear around the decimal point. **NOTE:** The *milliseconds* value may be ignored if the system does not support such granularity.

Example time "limit-values" are:

```
center, tab(); 11.1234 : 58 : 21.29; - 1234 hrs 58 mins 21.290 secs
12345 seconds 121.1; - 121.100 seconds 59:01; - 59 minutes and 1 second
```

For all other *finite* limits (with the exclusion of the *nice-value*), the acceptable syntax is:

```
.fraction [units]
```

or

```
integer [.fraction] [units]
```

where the "integer" and "fraction" tokens represent strings of up to eight decimal digits, denoting the obvious values. In both cases, the "units" of allocation may also be specified as one of the case insensitive strings:

```
center, tab(); 11. bytes w; words k; kilobytes (210 bytes) kw; kilowords (210 words) mb; megabytes (220 bytes) mw; megawords (220 words) gb; gigabytes (230 bytes) gw; giga-words (230 words)
```

In the absence of any "units" specification, the units of bytes are assumed.

For all limit types with the exception of the *nice-value*, it is possible to state that no limit should be applied. This is done by specifying a "limit" of "unlimited", or any initial substring thereof.

The complications caused by batch request resource limits first show up when queuing a batch request in a batch queue. This operation is described in the following paragraphs.

If a batch request specifies a limit that cannot be enforced by the underlying UNIX implementation, the limit is ignored, and the batch request operates as though there were no limit (other than the obvious physical maximums) placed upon that resource type. (See the "qlimit"(1)
command to find out what limits are supported by a given machine.)

For each remaining finite limit that can be supported by the underlying UNIX implementation that is not a CPU "time-limit" or UNIX "nice-value", the "limit-value" is internally converted to the units of bytes or words, whichever is more appropriate for the underlying machine architecture.

As an example, a working set size limit value of 321 megabytes would be interpreted as 321 x 2^20 bytes, provided that the underlying machine architecture was capable of directly addressing single bytes. Thus the original limit coefficient of 321 would become 321 x 2^20. On a machine that was only capable of addressing words, the appropriate conversion of 321 x 2^20 bytes / # of bytes-per-word would be performed.

If the result of such a conversion would cause overflow when the coefficient was represented as a signed-long integer on the supporting hardware, the coefficient is replaced with the coefficient of: 2^N-1 where N is equal to the number of bits of precision in a signed long integer. For typical 32-bit machines, this default extreme limit would therefore be 2^31-1 bytes. For word addressable machines in the supercomputer class supporting 64-bit long integers, the default extreme limit would be 2^63-1 words.

Lastly, some implementations of UNIX reserve coefficients of the form: 2^N-1 as synonymous with infinity, meaning no limit is to be applied. For such UNIX implementations, CXbatch further decrements the default extreme limit so as to not imply infinity.

The identical internal conversion process as described in the preceding paragraphs is also performed for all finite limit-values specified with a particular batch request.

After each applicable request limit has been converted as described above, the resulting limit is then compared against the corresponding limit as configured for the destination batch queue. If the corresponding batch queue limit for all batch request limits is defined as unlimited, or is greater than or equal to the corresponding batch request limit, the request can be successfully queued, provided that no other anomalous conditions occur. For requests that ask for a limit of infinity, the corresponding queue limit must also be configured as infinity.

These resource limit checks are performed irrespective of the batch request arrival mechanism, either by a direct use of the "qsub"(1) command, or by the indirect placement of a batch request into a batch queue via a "pipe" queue. It is impossible for a batch request to be queued in a CXbatch batch queue if "any" of these resource limit checks fail.

Finally, if a request fails to specify a "limit" for a resource limit type that is supported on the execution machine, the corresponding "limit" as configured for the destination queue becomes the "limit" for the request.

Upon the successful queuing of a request in a batch queue, the set of limits under which the request will execute is frozen and will not be modified by subsequent qmgr(8) commands that alter the limits of the containing batch queue.

**DIAGNOSTICS**

qmgr returns an exit status describing what the last qmgr command did. If there were no errors, the exit status is zero. If one or more of the operations failed, the exit status is the number of operations that failed. If a fatal error occurs and command completely fails, (ex, a syntax error), the exit status is one of the codes defined in <sys/exits.h>.

- **EX_USAGE** The command was used incorrectly, e.g., with the wrong number of arguments, a bad flag, a bad syntax in a parameter.
- **EX_NOHOST** The host specified did not exist.
- **EX_OSFILE** Some batch system file does not exist, cannot be opened, or has an error.
- **EX_TEMPFAIL** Temporary failure; retry the request at a later time.

NAME
qrun – force CXbatch request(s) to run.

SYNOPSIS
qrun request-id ...

DESCRIPTION
The qrun command forces each CXbatch request whose request-id is listed on the command line to immediately begin executing.

If spawning a force-run request would cause the run limit of the queue to be exceeded, CXbatch increases the run limit by one while the forced-run request is running.

CXbatch operator privileges are required to use this command. The target request(s) must reside in batch queues.

DIAGNOSTICS
qrun returns an exit status describing what it did. If there were no errors, the exit status is zero. If one or more of the requests were not run, the exit status is the number of requests that weren’t deleted. If a fatal error occurs and none of the requests are run (e.g., a syntax error), the exit status is one of the codes defined in <sysexits.h>.

EX_TEMPFAIL Temporary failure; retry the transaction at a later time.
EX_USAGE The command was used incorrectly, e.g., with the wrong number of arguments, a bad flag, a bad syntax in a parameter.
EX_OSFILe Some batch system file does not exist, cannot be opened, or has an error.
EX_NOPERM You did not have sufficient permission to perform the operation.
EXSOFTWARE Too many request ids were specified.

NAME
qsa - show accounting information on CXbatch requests

SYNOPSIS
qsa -r [ -QU ] [ -q queue ] [ -u username ] [ acct-file ]
qsa -x [ -QU ] [ -q queue ] [ -u username ] [ acct-file ]
qsa -a [ -QU ] [ -q queue ] [ -u username ] [ acct-file ]
qsa -s [ -QU ] [ -q queue ] [ -u username ] [ acct-file ]

DESCRIPTION
qsa processes CONVEX CXbatch accounting file and outputs data about requests. By default, qsa reads from /usr/adm/batchacct. Another file may be optionally specified on the command line.

qsa operates in one of four modes specified by the following command line flags:

r Raw mode. Accounting records are formatted and written to the standard output.

x Extended mode. Accounting records are processed, formatted and written to the standard output. This mode differs from raw mode in that time spent waiting in queue, time spent executing, and turnaround time are calculated and all time values are converted to ASCII using ctime(3).

a Averaging mode. Accounting records are processed and averages for turnaround time, time waiting in queue, execution time, CPU time in user mode, CPU time spent in system, and I/O operations performed are written.

s Summing mode. Accounting records are processed and totals for turnaround time, time waiting in queue, execution time, CPU time in user mode, CPU time spent in system, and I/O operations performed are written.

At least one of these mode flags must appear.

Constraint flags control which records qsa processes. If none are present, qsa processes all records in the accounting file. Using these flags, the user may specify records by queue, by user, or by both. The following flags specify constraints:

Q All queues. Accounting records are processed grouped by each queue appearing in the accounting file. This flag may not appear with the -q flag.

q queue Specific queues. Accounting records are processed grouped by queues specified in one or more occurrences of this flag. This flag may not appear with the -Q flag.

U All users. Accounting records are processed grouped by each user appearing in the accounting file. This flag may not appear with the -u flag.

u username Specific users. Accounting records are processed grouped by users specified in one or more occurrences of this flag. This flag may not appear with the -U flag.

DIAGNOSTICS
qsa returns an error status describing what it did. If there were no errors, the exit status is zero. If a fatal error occurs then the exit status is one of the codes defined in <sys/exits.h>.

EX_USAGE One of the following incorrect usages was specified: More that 20 occurrences of the -q or -u options, respectively, none or more than one of the mode options, -r, -x, -a, -s, was specified, the -Q option was specified with the -q option, the -U option was specified with the -u option, or an invalid option was specified.

EX_DATAERR The accounting file was not a regular file.
EX_NOINPUT Cannot open accounting file or unable to access CXbatch database files.

NAME
qsnapshot – dump the current CXbatch queue or network configuration

SYNOPSIS
qsnapshot [-m]

DESCRIPTION
qsnapshot dumps the current CXbatch queue or networking configuration as a series of qmgr(8) or qmapmgr(8) commands. The resulting output is suitable as input to a subsequent qmgr(8) or qmapmgr(8) command. By default, qsnapshot dumps the CXbatch queue configuration. The -m option causes the qmapmgr(8) network database to be dumped instead.

The qsnapshot command is useful for copying the CXbatch configuration from one system to another or (by editing the output) duplicating a complex queue(s) on the local system.

Recreating CXbatch Databases
There are no qmgr(8) or qmapmgr(8) commands which clear out the old configurations from their respective database. If it is necessary to do this, shutdown CXbatch and use one or both of the commands given below. Recreating the qmapmgr database will require you to recreate the qmgr database if any of the MID to machine mappings are changed. Some MID's may be referenced in the qmgr database. These commands should be executed with caution, as should any recursive rm(1) commands containing wildcard characters.

To empty the qmgr(8) database:

    rm -f /usr/spool/nqs/private/root/database/*

To empty the qmapmgr(8) database:

    rm -f /etc/nmap/*

DIAGNOSTICS
qsnapshot returns an exit status describing what it did. If there were no errors, the exit status is zero. If a fatal error occurs, then the exit status is one of the codes defined in <sysexits.h>.

EX_USAGE The command was used incorrectly, e.g., with the wrong number of arguments, a bad flag, a bad syntax in a parameter.

EX_OSFILE Some batch system file does not exist, cannot be opened, or has an error.

NAME
qwatch – watch status of CXbatch queue(s)

SYNOPSIS
qwatch [-i interval] [-c count]

DESCRIPTION
qwatch monitors the status of CONVEX CXbatch and periodically reports statistics about queues
and/or requests.

Initially, qwatch displays queue headers for the first five queues. If there are more than five
queues, additional pages can be displayed by typing the number of the desired page. Only five
pages (25 queues) can be display by qwatch.

By typing the letter (a-y) corresponding to a queue, you can monitor the activity of that queue.
The first page of the requests within the selected queue is displayed along with the queue header.
If there are more that 16 requests in the queue, additional pages can be displayed by typing the
number of the desired page. Only nine pages (144 requests) can be displayed by qwatch.

The command line switches, which may be given in any order, are:

- c count If count is positive, qwatch automatically exits after count screen updates have
  been completed. If count is 0, qwatch keeps updating until stopped. The default
  value for count is 0.

- i interval Specifies how many seconds to wait between each screen update. The default is
  five seconds.

The following keys are interpreted by qwatch:

<SPACE>
<RETURN> Force qwatch to update the screen and restart the timer.
<CTRL-L> Replot the screen.
[1-9] Select a display page. (Only pages with information on them may be selected.)
[a-y] Select a queue. (Only available from queues display page.)
- Return to queues display page from requests display page.

The SIGINT signal, usually generated by <CTRL-C> or <DEL>, is used to exit qwatch.
Additionally, qwatch can be interrupted and later resumed with the SIGTSTP signal, which is
typically generated by <CTRL-Z> from csh.

QUEUE STATE INFORMATION
Refer to the qstat(1) manpage for an explanation of the information displayed by qwatch.

DIAGNOSTICS
qwatch returns an exit status describing what it did. If there were no errors, the exit status is
zero. If a fatal error occurs, then the exit status is one of the codes defined in <sysexits.h>.

EX_UNAVAILABLE
The terminal does not support the capabilities necessary for qwatch to work
properly.

EX_USAGE The command was used incorrectly, e.g., with the wrong number of argu-
ments, a bad flag, a bad syntax in a parameter.
